## THERMAL APPLICATIONS NOTE

### Polymer Heats of Fusion

Roger L. Blaine

TA Instruments, 109 Lukens Drive, New Castle DE 19720, USA

The heat of fusion of 100 % crystalline polymer is required to obtain percent crystallinity by differential scanning calorimetry (1). Polymer reference materials with 100 % crystallinity are rarely available for comparison purposes. Fortunately, the heats of fusion values for 100 % crystalline polymers may be determined by indirect methods such as extrapolation using the Flory equation (2). Wunderlich and co-workers (3) have created tables of best estimate values for the heats of fusion for a wide variety of linear polymers with values reported in joules per mole of repeat unit. To be useful for thermal analysis purposes, these enthalpy values need to be normalized to mass. Table 1 includes the mass normalized enthalpy of fusion values commonly used in DSC determinations.
